

Real-time Weather Rendering System

Project documentation

Field of Studies:	BSc in Computer Science
Specialization:	Computer perception and virtual reality
Author:	Matthias Thomann
Supervisor:	Prof. Urs Künzler
Date:	April 8, 2021
Version:	1.0

Abstract

Clouds contribute a great deal to the overall ambience in games and can be the cherry on top by filling the sky with life. To get as close as possible to real clouds, this project engages in researching and prototyping a procedural, volumetric cloud shader.

In order to achieve volumetric rendering, the document dives into the concept of ray marching, a group of methods used to render a 3D data set inside a container box to make it appear volumetric. Several variants of it are expanded on, like constant step, traditional, and sphere-traced ray marching. Additionally, to account for perception of depth, the volume can be shaded with the aid of surface normal estimation.

In the second part, 2D and 3D noise generation algorithms like Perlin's noise and the Voronoi algorithm are explained in detail. With fractal Brownian motion, the different layers of noise are then merged into one highly detailed noise texture.

At last, the goal of the project was to create prototypes in Unity displaying both volumetric rendering and noise algorithms, of which all were created successfully. Prepared with the combined knowledge of the research results and prototypes, a final shader was created, able to render a completely procedural and volumetric cloudscape.

For future work, the shader could be expanded into a fully-fledged weather simulation system with meteorologically accurate formation of clouds, rain, snow and much more.

1 General

1.1 Purpose

During this project, all gathered information and knowledge about the researched algorithms and techniques are written down. All prototypes and the final results are documented and compared with real photographs of clouds.

1.2 Audience

This document is written with the intent to further expand existing knowledge about the topic, hence it requires a fundamental knowledge about computer graphics and rendering.

1.3 Revision History

0.1	March 25, 2020	Matthias Thomann	Initial draft
0.2	April 05, 2020	Matthias Thomann	Cloud classification added

2 Natural Clouds

Clouds are a substantial part of Earth’s weather. They provide shade from the glistening sun on hot days and reflect the heat at night, keeping the ground warmer. For a layman, clouds are comprehensible and useful indicators for telling the weather. If they are dark and low-hanging, they usually bring rain. If they are puffy and scarce, they predict fair weather ahead.

2.1 Convection

In meteorology, convection describes the event of atmospheric motions in the vertical direction. Hot air rises from Earth’s surface in form of bubbles, which are called *thermals*. As the altitude increases, the thermals cool down. At some point, the warm air mixes with the surrounding colder air, after which its moisture condenses and starts forming clouds [1].

Figure 1: Lifting by convection.

2.2 Classifications

In order to create a weather rendering system that is able to display many different cloudscapes, all types of clouds have to be understood first. The World Meteorological Organization (WMO) describes ten distinct cloud classifications. For each of those, there are further subtypes. For simplicity, those subtypes will be disregarded in this project.

Figure 2: Distinct classifications of cloudshapes in the troposphere [2].

This graphic above provides an excellent overview of all distinct cloud types. Each type is depicted in its signature shape and marked with the scientific name and abbreviation. Natural clouds are typically identified by two major factors: shape and altitude. The altitude, which is the distance from sea level to the cloud, is further split into three categories "low", "mid" and "high". This corresponds to the altitude at which the cloud usually forms, up to twelve kilometers above ground.

All of those clouds are formed in the troposphere, Earth's lowest atmospheric layer. Certain clouds may occur in the stratospheric or even the mesospheric layer, but they are usually a rare sight. Therefore, those clouds will not be covered in this project.

2.2.1 Cirrus

Cirrus clouds consist of thin, hair-like strands. They fall into the "high" altitude group and mostly appear in a bright white color, although they may take on the colors of the sunset or sunrise. Typically, they are formed when water vapor undergoes desublimation, the process in which gas turns into solid. This occurs when the water vapor freezes rapidly at high altitudes, turning into ice crystals.

However, cirrus clouds can also form from air that flows outwards of thunderstorms.

Figure 3: Cirrus clouds [3].

Interpretation: Fair weather, but they might announce the arrival of warm front in 12-24 hours, which is often preceded by rain several hours in advance. Even though cirrus clouds indicate precipitation, they themselves do not produce rainfall [4].

2.2.2 Cirrostratus

Cirrostratus clouds are similar to the cirrus clouds, only that they are even thinner. Those clouds depict more of a veil than a single cloud shape. They form under the same conditions as the cirrus clouds and can cover a massive area of the sky, spanning thousands of kilometers.

Cirrostratus clouds sometimes produce white rings or arcs of lights around the sun or the moon called the *halo phenomenon*. Sometimes, the cirrostratus clouds are so thin that the halo is the only way to tell if there are cirrostratus clouds.

Figure 4: Cirrostratus clouds [5].

Interpretation: Fair weather, but they indicate a warm front within one or two days, bringing precipitation [6].

2.2.3 Cirrocumulus

Similar to the other clouds of the cirrus-family, the cirrocumulus are composed of ice crystals and formed at high altitudes. They are made up of many small, white, puffy clouds called *cloudlets*. Their wooly look give the cloud the name *cumulus*.

Cirrocumulus clouds are relatively rare, as they are naturally only formed when a turbulent vertical current meets a cirrus cloud layer. The cirrus cloud then disperses into many cloudlets.

Figure 5: Cirrocumulus clouds [7].

Interpretation: They do produce precipitation, but it never reaches the surface, meaning that cirrocumulus clouds are typically associated with fair weather [6].

2.2.4 Altostratus

The name for this grey, uniform sheet of clouds consists of the latin words *alto* (height) and *stratus* (layered), summing up their appearance accurately. Altostratus clouds usually cover the whole sky and form a dull blanket of monocolored clouds with very few features. The sun- or moonlight may shine through them, but will most likely not be strong enough to cast defined shadows.

Figure 6: Altostratus clouds [6].

Interpretation: Altostratus clouds usually indicate precipitation, even more so if they are preceded by cirrus clouds. If the precipitation increases in persistence and intensity, the altostratus clouds will lower and thicken into nimbostratus clouds.

2.2.5 Altocumulus

As with the cirrocumulus clouds, altocumulus clouds consist of small, puffy, white and grey cloudlets. These cloudlets are usually slightly bigger than the ones of the cirrocumulus cloud. It is easy to tell them apart, as the altocumulus cloudlets are usually more grey than white and are shaded on one side. Altocumulus clouds can form through the dispersion of altostratus clouds or through convection (see subsection 2.1).

Figure 7: Altocumulus clouds [8].

Interpretation: Usually, they are found in settled weather. They do not produce precipitation that reaches the surface.

Glossary

Altitude A vertical distance measurement, in this context specifically the distance from sea level to the given object. 2, 3, 4

Cloudlet Small, white, puffy clouds that come in large quantities, together forming a cloud of the cumulus family. 4, 5

Convection The process of warm air rising from the surface and cooling at higher altitude, of which the moisture is then condensed into clouds. 2, 5

Desublimation The process of gas transitioning to liquid without passing through the liquid phase. 4

Fractal Brownian motion Different iterations of continuously more detailed noise layered on top of each other. i

Halo phenomenon White or colored rings or arcs of light around the sun or the moon, produced by cirrostratus clouds. 4

Noise A randomly generated pattern, referring to procedural pattern generation. i

Precipitation Rainfall. The result of atmospheric water vapor that has been condensed and now falls from clouds. 4, 5

Procedural Created solely with algorithms and independant of any prerequisites. i, 6

Ray marching Ray marching is a type of method to approximate the surface distance of a volumetric object, where a ray is cast into the volume and stepped forward until the surface is reached. i

Surface normal A *surface normal* or *normal* is a vector which is perpendicular to a given geometry, like a triangle or polygon. i

Thermal Relating to convection, "thermal" is what the hot, rising air is called. 2

Volumetric This describes a technique which takes a 3D volume of data and projects it to 2D. It is mostly used for transparent effects stored as a 3D image. i

Water vapor Evaporated water in a gaseous form. 4

Weather rendering system The Unity application that is implemented during this project. It takes in live data from a weather service and uses topological elevation models to create a weather simulation, which is then rendered and up for comparison with live photographs. 2

WMO A specialized agency conducting atmospheric science, climatology, hydrology and geophysics. 2
